Container.Q: No gui and No CLI commands in linux I am trying to make a Linux system to capture the command line input from a user. I am using the below code to achieve this. /* * In this file the characters are not input from the user, * But they are sent to stdin of the parent process. */ char *username = (char*)malloc(100); strcpy(username,"user"); int fd = open("/dev/tty", O_RDWR); printf("%d ", fd); char buffer[10]; read(0, buffer, 10); close(fd); printf("Username : %s ", username); return 0; This is working fine. However the problem is, the Linux system (Ubuntu 12.04) has no command line based commands, and it is only a terminal. Is there any way to make a system that accepts user input through the terminal and send it to the process? A: You can use a library like getty to provide a login shell. This uses a tty that supports input (including echo and bash), and a serial console that is connected to your embedded system.
